# Using Simulation as a Tool for Coker Troubleshooting – the KBC Approach

*Ranjit Bhise*

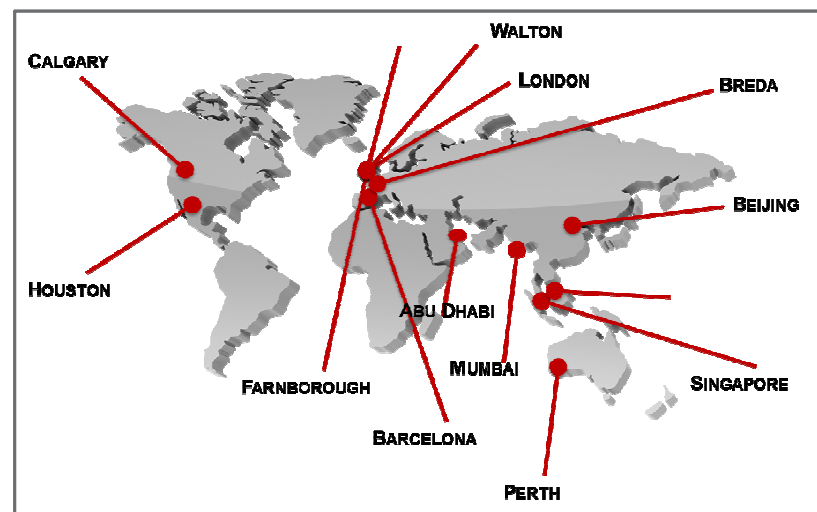

*KBC India*

SUPERIOR RESULTS. SUSTAINED.

- KBC Introduction
- Coker Case Studies
- KBC Software Portfolio
- Petro-SIM™ and Rx-SIM
- DC-SIM™ and Drum Modelling

# KBC Advanced Technologies

- KBC is now a Yokogawa company
- KBC is a UK based leading independent consulting and technology group established in 1979
- We deliver competitive advantage in the Oil and Gas industry through **business performance improvements/asset value recognition, strategic solutions and Petro-SIM software**

# Case Study 1: Drum Pressure Optimisation

## Client Situation

Indian Refinery Coker heavy distillate was high in CCR limiting refinery capacity..

## Project Implementation Approach

- Unit operating at +125% of design feed
- High CCR in HCGO > 1.5 wt%
- Downstream Hydrocracker constrained by feed filtration cycles
- Internal drop of HCGO increased unit CFR, dropped unit feed rate and ultimately reduced Crude throughput to refinery

## Key Findings from Simulation Model

- High Vapor Velocities in drum
- High 'C' factor of drum. 'C' factor is a ratio of Vapor and liquid densities and Vapor Velocities
- Vapor and Liquid densities depend on Unit operating capacities, Drum temperature, Pressure
- 'C' factor is also feed quality dependent, foamover tendency and cycle time
- Typically drum vapor velocities should be limited to **0.5 ft/s** and 'C' factor should be limited to **0.3 ft/s**
- Tendencies to push that 'last bottom of the barrel' in Cokers lead to new operating challenges

$$C_s = u_s \sqrt{\frac{\rho_v}{\rho_L - \rho_v}}$$

**KBC Kinetic model of Coker drum helps in identifying these new constraints**

# Case Study 1: Drum Pressure Optimisation

## Client Situation

Indian Refinery Coker heavy distillate was high in CCR limiting refinery capacity

## Use of Model for Recommendations

- Calibrated base case model was used to run over 2 dozen Predict cases were compared by varying independent variables such as Drum Pressure, Heater COT (Every Coker is limited here!), unit capacity, recycle ratio...
- Optimum Drum pressure was selected such that it limits loss of yield (high coke make) and reduction of GRM within agreed envelope
- Drum pressure was increased by 30% by changing WGC suction pressure. This saw HCGO CCR reduction by 80% and helped to stabilise HCR bed DP. There was a debit in terms of increased Coke make
- Refinery crude processing rate was normalised (*Revenue!!*)
- Subsequently Fractionator internals were modified (Changeover to Packing from Shed deck trays) as advised by KBC. At higher throughputs packings help to reduce entrainment with optimum 'wash and wetting rates'

## Results

Improved refinery reliability and accrued refinery revenue by 20-25 million USD over 6 months

# Case Study 2: Velocity Steam and Heater Optimisation

## Client Situation

Client had high tube fouling rate on a newly commissioned Coker heater

## Project Implementation Approach

- Skin temperatures rise per day was double at 4°F
- High Fouling rates reduced run length between decoking from 6 to 3 months
- Refining constrained on crude capacity

## Key Findings from Simulation Model

- Velocity steam rate is feed quality, heater tube length, radiation box design, injection point and heater ' $\Delta P$ ' dependent
- Feed Asphaltenes (SARA) along with KBC proprietary '*Colloid Instability Index*' factor (part of Heater model) was used for tuning
- Velocity steam optimisation reduces 'Peak Oil Temperatures' in outlet preceding coils. But very high rates can imply Foam over & Fractionator overhead cooling limitations
- Client implemented KBC recommendations of Velocity steam variation and temperature measurement source

## Results

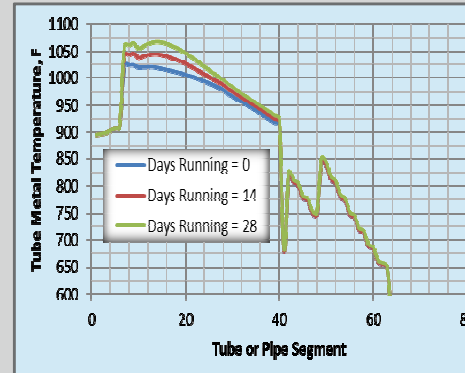

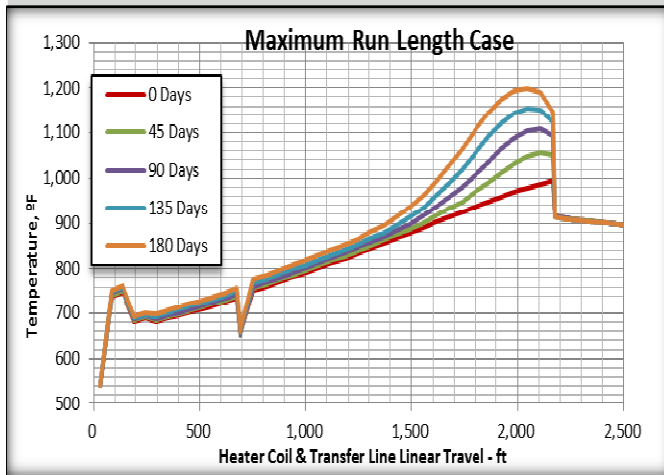

Increase in Heater run length and reduction in Skin Temperature rise by 2°F

# Case Study 2: Velocity Steam and Heater Optimisation

## Client Situation

Client had high tube fouling rate on a newly commissioned heater

## Simulation Aid

- Such and similar conclusions (graphs) are easy to plot and review using Coker heater simulation model.
- Heater model Calibration and tuning is based on operating and engineering data
- Variation of operating conditions in predict mode defines process optimisation

# Case Study 3: Reducing Coker Recycle

*DC-SIM ability to predict Quality and quantity of 'Column Recycle stream'*

A Yokogawa Company

## Client Situation

A Middle East Refiner Coker heavy distillate had high overlap with recycle stream

## Project Implementation Approach

- Overhead 'Quench', Heat loss in overhead line and tower Wash zone design all contribute to recycle
- Processing heavy Refinery Slops in fractionator also contributes to higher recycle
- Excessive drop in temp of drum vapor adds by quenching adds to additional recycle.
- Overhead quench liquid contributes to 30% of Recycle with rest coming from Wash Zone of fractionator
- Processing heavy Blowdown liquid in fractionator flash zone also adds to higher recycle
- Flash zone Packing v/s sieve and/or Shed deck influence Recycle

- Having large number of Trays in flash zone wash section requires additional wash too keep trays wet and avoid coking. This contributes to Recycle

***All scenarios can be Simulated coupled with Kinetic Model***

# Case Study 3: Reducing Coker Recycle

*DC-SIM ability to predict Quality and quantity of 'Column Recycle stream'*

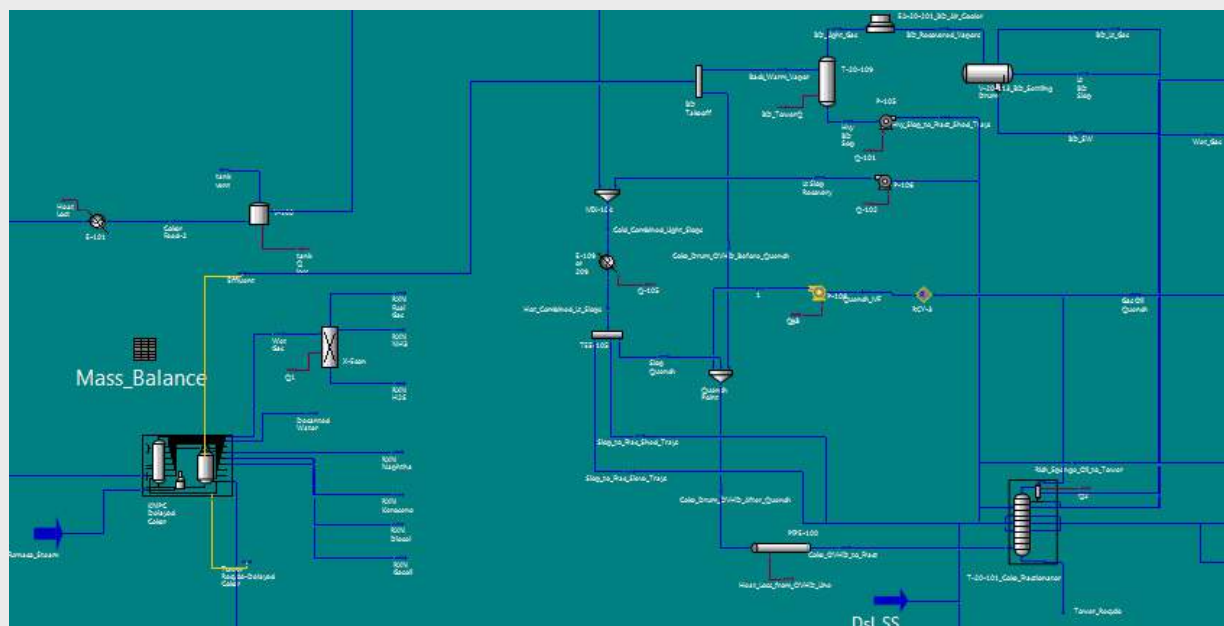

A Yokogawa Company

## Client Situation

A Middle East Refiner Coker heavy distillate has high overlap with recycle stream

## Key Findings and Recommendations

- DC-SIM reactor model and Petro-SIM flowsheeting techniques were used to model
  - Blowdown system,
  - Overhead vapor pipe segment
  - Quench stream
- Petro-SIM fractionator bottoms recycle stream quality can be easily compared with Kinetic model generated recycle stream quality gives confidence of a good base case

## Results

Setting up Base model is key to success of simulation application to actual operations

# Case Study 3: Reducing Coker Recycle

*DC-SIM ability to predict Quality and quantity of 'Column Recycle stream'*

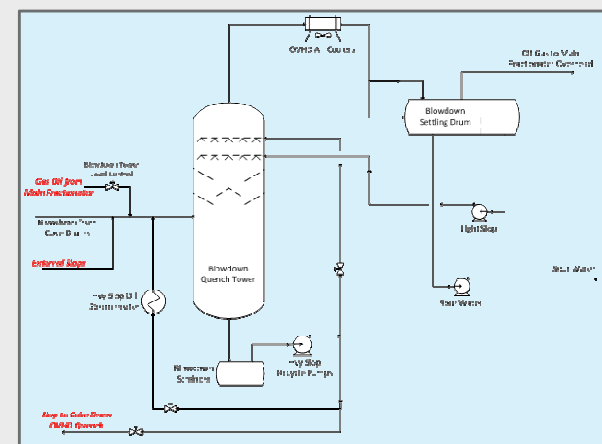

A Yokogawa Company

## Client Situation

A Middle East Refiner Coker heavy distillate has high overlap with recycle stream

## Key Findings and Recommendations

- Simulating flash zone conditions using combination of Drum vapor stream + Quench helped in minimising 'Wash' to trays. However it can run into risk of Trays or packing coke up, use Tray designer guidelines to optimise
- Delta changes in Drum Vapor properties (post quench) and recycle stream properties as output from simulation help in correctly representing Flash zone.
- Drum overhead line model, MF flash zone section model, PA adjustments for improved Vapor – Liquid traffic, all helped to optimise & reduce CFR with reduction in overlap
- KBC suggested
  - Slops diversion to Blowdown tower rather than Fractionator
  - Flash zone modification with part open spray chamber & reduction in number of shed deck trays

Recycle Reduction	2-3%
Delta Coke Reduction	0.8%

## Results

Expected refinery wide benefit was 5.0 m\$/y. Client will be implementing it as a part of Revamp

## *Petro-SIM*<sup>TM</sup>

- Steady-state and dynamic process simulator for unit operations

## *SIM Reactor Suite*<sup>TM</sup>

- Reactor Kinetic modelling in refining and petrochemicals

## *Energy-SIM*<sup>TM</sup>

- For Utility system modelling

## *Multiflash*<sup>TM</sup>

- Comprehensive Phase behavior, PVT and flow assurance package

## *Maximus*<sup>TM</sup>

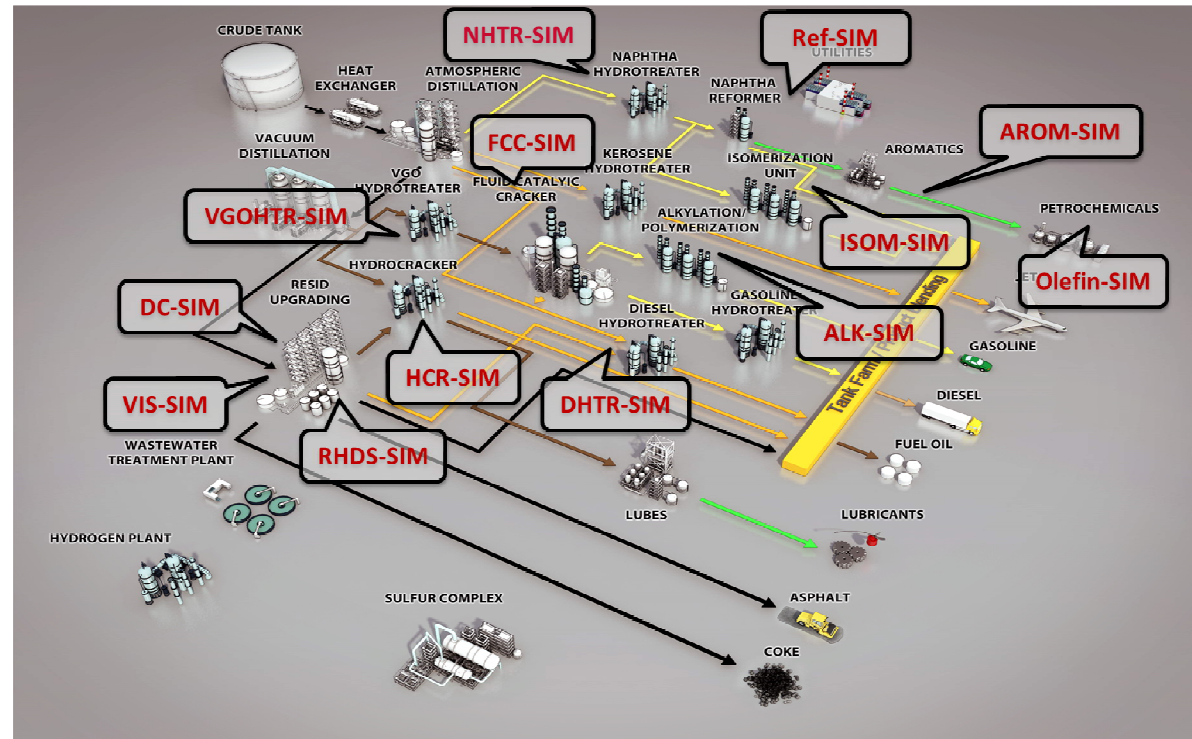

- Thermal and hydraulic network simulator for Oil & Gas fields

# KBC Petro-SIM and Rx-SIM

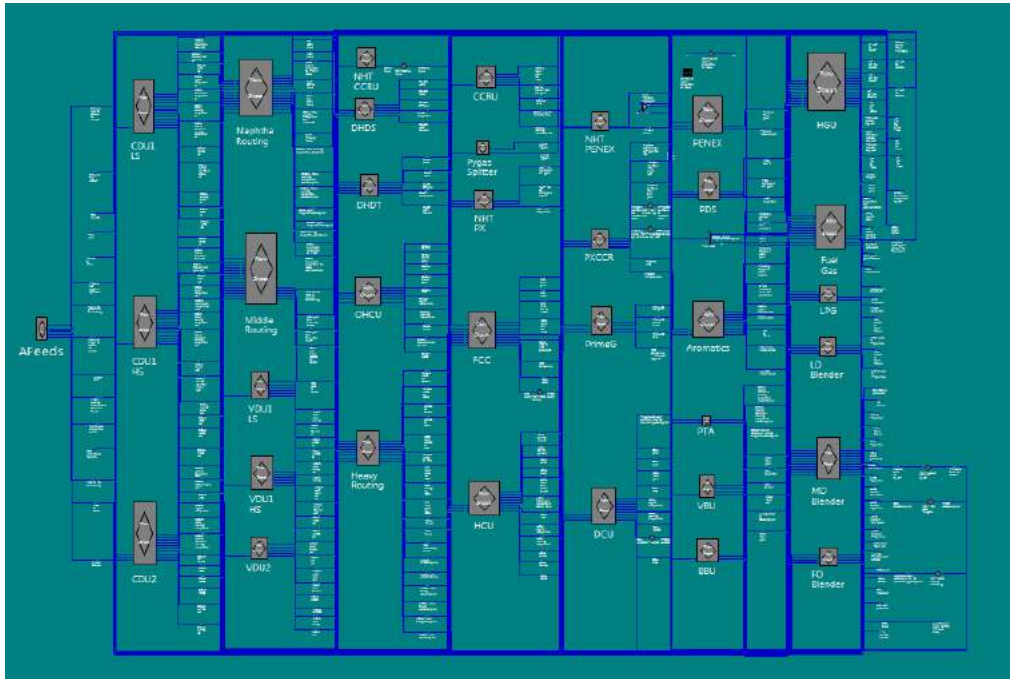

A Yokogawa Company

- Full function process simulation platform backed by KBC consulting experience
- Refinery wide flowsheet modelling
- Integrated with other technologies, historians, databases
- Leader in reactor kinetics modelling
- Backbone for profit improvement studies, LP vectors generation

Regular version updates with improved reactor kinetics and features using client feedback

***V.7.0 release next year***

Refinery units integration into flowsheet and transition into workbook makes it a powerful case comparison tool

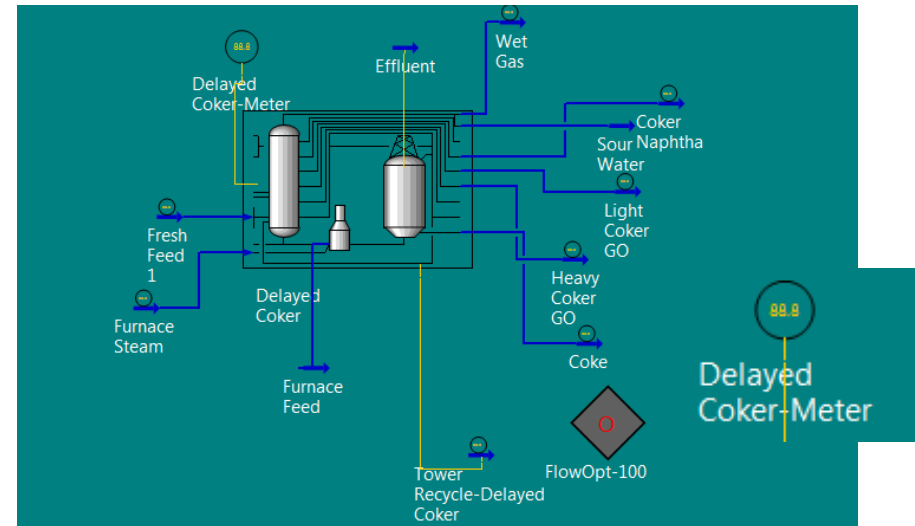

# DC-SIM and Coker Heater Set-up

## Heater Model

- Rigorous tube by tube calculations
- Can be calibrated to match Coker reactor heater effluent stream
- Tuning by Heat flux, tube dimensions, skin T, metallurgy....

Tube Heat Balance Closure

☐ Calculate equal fluxes in all tubes

☐ Specify tube by tube heat flux: Fixed Values

☒ Specify tube by tube heat flux: Flux Profile

☐ Specify tube by tube heat fractions

☒ Inlet Tube T initialization only

Update Flux

- Drum model has in-built rigorous fractionator Bottom ckt that helps to predict correct quality and quantity of CFR
- Although steady state, but works on snapshots at time intervals of drum cycle
- 'Foam-over' tendency, 'Drum C-factor', 'Vapour Velocity', 'Coke Outage level' assessment are some critical parameters that can be correctly predicted

# DC-SIM Data Input, Calibration and Results

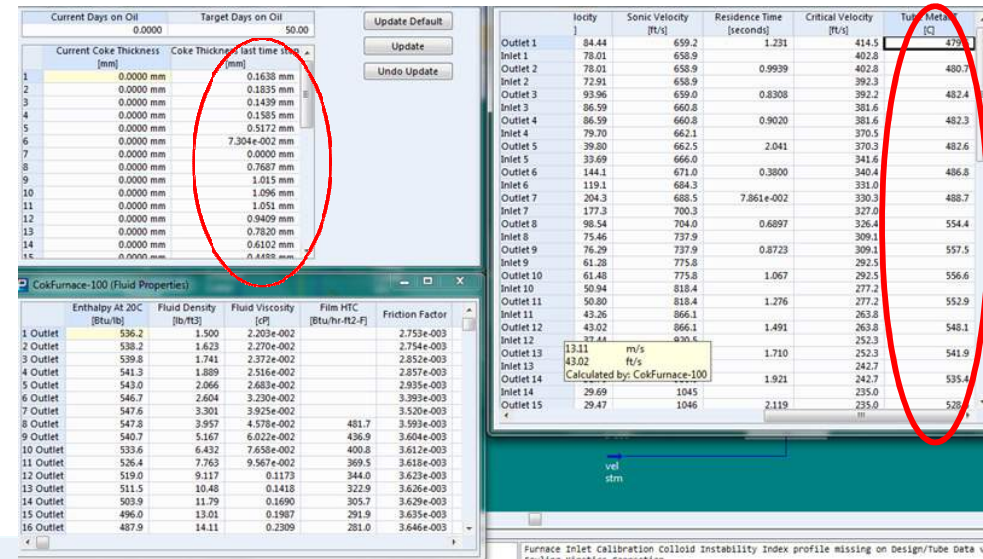

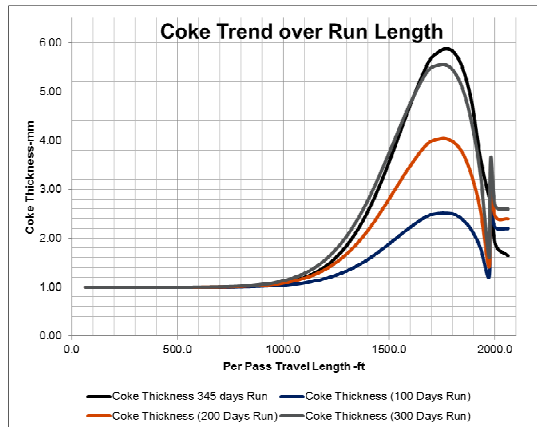

- 'Once through' and conventional designs can be modelled
- Predicts % cracking at end of heater transfer line
- Flexibility to model 'extra low recycle' operation
- Feed and impurities distributed within 50F pseudo components
- Model estimates coke 'S' & 'N' from balance. Coke quantity from feed CCR
- 1<sup>ST</sup> Order reaction kinetic rates separately for cracking and coking using 'Arrhenius equation'

- Drum Liquid hold-up results provides insight into vapour/liquid equilibrium over the coke surface that ultimately helps to predict correct VCM & HGI properties of Coke
- Drum foaming tendency predictions is another feature to troubleshoot operations

# Coker Heater Modelling

- Based on actual geometry, tube-by-tube heat balance, pressure drop, coke laydown in tubes and transfer line and run-length predictions
- Coke formation is a function of bulk and film temperatures
- Tube flow regime helps in optimising 'Velocity Steam', extending de-coking cycle time, reducing peak oil temperatures of tubes

- Pressure drop calculations are based on widely accepted '*Beggs & Brill*' method
- Heat flux calculations are based on '*Boltzmann-Levans*' method that uses flue gas temperature to iterate and provide radiant flux
